

Don't be Poor!!!

By Connor Lynch, Jose Pena, and Kyle Kotaska
CEN 4010: Software Engineering taught by Dr. Upulee Kanewala

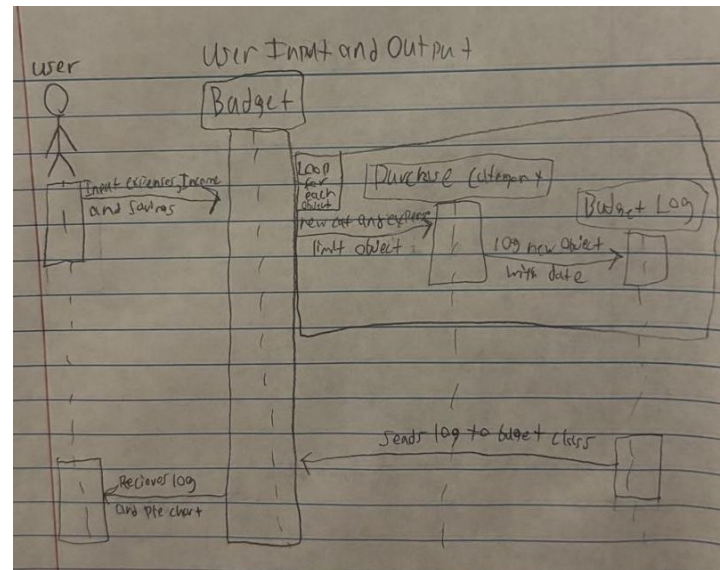

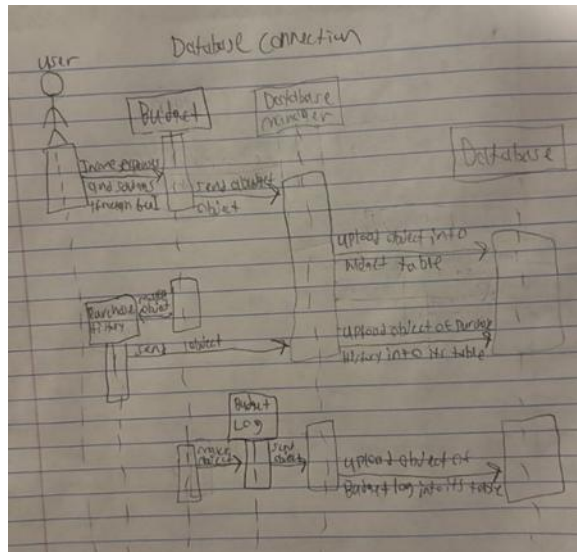

Problem: We are trying to show our users how they spend their money along with suggestions and tips to help them save money due to their expenses.

Motivation: This problem is important to solve because so many people in this world have trouble sustaining their money and keeping afloat. People who live paycheck to paycheck. This app reduces this problem by educating the users about their expenses and how to help them.

Solution: Our solution includes showing our users a pie chart with information on their expenses and how their income is being used. Then their expenses will be examined by the program and will output suggestions according to how their expenses are, like suggesting cutting down on fast food, spend less on entertainment, or even use interest from their savings to pay some of their debt.

Technologies: We used Eclipse, SQLite, Word, and GitHub

Next Steps: The main next steps we plan to implement will be a GUI and handling input and output to the user.

Program:

Use case with specific values

1.The program asks for input.

3.The program will show a pie chart, where it will show 40% for rent, 40% for bills, and 20% for rent. The program will then suggest reducing bills then try to reduce grocery spending. The program will calculate the savings interest and suggest using that money towards the debt (since there is a debt) $6\% \times 2000 = 120$. This \$120 will be used to help with their debt. The user's data will be put in the database, specifically their information will be within a budget table, budget log, and their own purchase history.

5.The program will show a pie chart, where it will show the percentages according to the amount of money for the reasons they spend the money. The program will then suggest reducing spending in miscellaneous, then in fast food next. Finally, the program will tell the user to use the extra income and put it in the savings. Another set of information will be inserted into the database.

7. The program will ask for input

User:

2.The user puts in 2000 income, 2000 savings, 2500 expenses (1000 rent, 1000 bills, 500 groceries). The user will be able to put the amount of each expense and click an option with the drop down to choose the reason why they are allocating the money (as shown above).

4.The user will change their input to 6000 income, 150 savings, 5000 expenses (2000 rent, 1000 groceries, 500 bills, 500 car payments, 500 fast food, 500 miscellaneous).

6. The user doesn't insert anymore input.

8. The user closes the window.
